Synthetic Study of Fatigue Detection

Abstract

The proposed approach processes physiological signals collected from participants. Each recording is segmented into fixed windows and normalized before analysis. Results are reported on a held out test split to avoid optimistic estimates.

1. Introduction

The proposed approach processes physiological signals collected from participants. Each recording is segmented into fixed windows and normalized before analysis. Results are reported on a held out test split to avoid optimistic estimates.

2. Method

The method consists of the following steps:

- Signal filtering
- Feature extraction
- Model training

2.1 Dataset

The proposed approach processes physiological signals collected from participants. Each recording is segmented into fixed windows and normalized before analysis. Results are reported on a held out test split to avoid optimistic estimates.

3. Conclusion

The proposed approach processes physiological signals collected from participants. Each recording is segmented into fixed windows and normalized before analysis. Results are reported on a held out test split to avoid optimistic estimates.
